(54) Resistive finger detection for fingerprint sensor

(57) Within a capacitive fingerprint detection device, finger detection is provided by a plurality of resistive grids overlying the fingerprint sensor electrodes to measure the resistance of the finger placed on the sensor surface. A finger placed on the sensor surface connects the resistive rids and allows the skin resistivity to

be measured. The measured resistance is compared to a reference resistance or range of resistances to determine whether the measured resistance matches the expected bio-characteristics of living skin tissue. The finger detection thus provides anti-spoofing protection for the fingerprint detection device.

EP 1 187 057 A2

Description

[0001] The present invention relates to fingerprint detection and recognition and in particular to finger detection within integrated circuit devices employed for fingerprint-based identification and security mechanisms.

[0002] Fingerprint detection and recognition has become a widely implemented identification and security (verification) measure for a variety of applications, including credit card usage, governmental licensing and registration, and premises access control. Integrated circuit fingerprint sensors used in such detection usually contain a two-dimensional array of sensing electrodes at a pitch substantially smaller than the size of the lines on the skin surface of a fingertip, allowing an image of the fingerprint pattern to be acquired for processing, analysis and comparison.

[0003] The structure of a typical electronic fingerprint sensor is depicted in **Figure 4**. Fingerprint sensor 402 includes a planar array of sensing electrodes 404 conductively coupled to detection and image capture circuitry (not shown). Sensing electrodes 404 may be covered by a protective layer 406 against which the skin surface 408 of the fingertip is placed. Ridges 410 and valleys 412 formed by the lines on the fingertip skin surface 408 are then detected utilizing sensing electrodes 404.

[0004] Fingerprint detection is most commonly achieved at least partially through capacitive coupling with the finger. In such embodiments, skin surface 408 and sensing electrodes 404 each form a capacitor having a capacitance proportional to the distance between a respective sensing electrode 404 and the overlying skin surface 408. Thus, for example, the capacitance measured by sensor 402 at a point near the top of a fingerprint ridge 410 by a sensing electrode separated from skin surface 408 by a distance $d_{x,y}$ (where x and y denote the position of the respective sensing electrode within the two-dimensional sensor array) will differ from the capacitance measured through another sensing electrode at a point near the bottom of a fingerprint valley 412, where the intervening distance $d_{x,y+2}$ is greater. In this manner an electronic image of the fingerprint may be captured for further processing.

[0005] Fingerprint detection normally involves a relative or comparative process, in which a characteristic such as capacitance) at one sensing electrode within the array is processed relative to similar measurements by the other sensing electrodes. As a result, the fingerprint sensor is subject to attack by "spoofing," or presentation of the appropriate fingerprint pattern by an unauthorized individual. For example, the simplest spoofing technique might involve use of a finger severed from an authorized individual for that purpose.

[0006] It would be desirable, therefore, to protect against unauthorized uses of fingerprint patterns being employed in order to circumvent fingerprint-based identification and security mechanisms.

[0007] Within a capacitive fingerprint detection de-

vice, finger detection is provided by a plurality of resistive grids overlying the fingerprint sensor electrodes to measure the resistance of the finger placed on the sensor surface. A finger placed on the sensor surface connects the resistive grids and allows the skin resistivity to be measured. The measured resistance is compared to a reference resistance or range of resistances to determine whether the measured resistance matches the expected bio-characteristics of living skin tissue. The finger detection thus provides anti-spoofing protection for the fingerprint detection device.

[0008] The novel features believed characteristic of the invention are set forth in the appended claims. The invention itself however, as well as a preferred mode of use, and further objects and advantages thereof, will best be understood by reference to the following detailed description of an illustrative embodiment when read in conjunction with the accompanying drawings, wherein:

Figure 1 depicts a fingerprint sensor circuit employing resistive finger detection in accordance with a preferred embodiment of the present invention;

Figures 2A-2B are diagrams of fingerprint sensor arrays including resistive finger detection in accordance with a preferred embodiment of the present invention;

Figure 3 depicts a circuit diagram for a finger detection circuit employed within a fingerprint sensor in accordance with a preferred embodiment of the present invention; and

Figure 4 is a diagram of a known capacitive fingerprint detection structure.

[0009] The following description details the structure, application and features of the present invention, but it will be understood by those of skill in the art that the scope of the invention is defined only by the issued claims, and not by any description herein. The process steps and structures described below do not form a complete process flow for manufacturing integrated circuits. The present invention can be practiced in conjunction with integrated circuit fabrication techniques currently used in the art, and only so much of the commonly practiced process steps are included as are necessary for an understanding of the present invention. The figures representing cross-sections of portions of an integrated circuit during fabrication are not drawn to scale, but instead are drawn so as to illustrate the important features of the invention.

[0010] With reference now to the figures, and in particular with reference to **Figure 1**, a fingerprint sensor circuit employing resistive finger detection in accordance with a preferred embodiment of the present invention is depicted. **Figure 1** depicts a block diagram of the

sensor circuit **102**, which is formed as an integrated circuit on a single die. A suitable sensor circuit **102** and its operation are described more fully in commonly assigned, copending application serial no. 09/040,261, entitled "CAPACITIVE DISTANCE SENSOR" and filed May 9, 1998, which is incorporated herein by reference.

[0011] Sensor circuit **102** includes I²C interface and control device **104**, which provides a bidirectional communication protocol enabling sensor circuit **102** to communicate with a controller, such as a microcontroller. I²C interface and control device **104** exchanges digital signals via control line **106** with controller circuitry (not shown) external to sensor circuit **102** in the example illustrated, although alternatively such control circuitry may also be integrated within sensor circuit **102**. Sensor circuit **102** also includes an array **108** of capacitive sensors for fingerprint acquisition by sensing distances between capacitive electrodes within the sensor array **108** and ridges and grooves on a finger placed in contact with sensor array **108**.

[0012] Sensor array **108** is coupled to the external controller circuit via synchronization line **110**. Through synchronization line **110** sensor array **108** provides synchronization signals allowing detected voltages representative of the capacitive value of individual capacitive electrodes within sensor array **108**, and therefore representative of the distance between the capacitive electrode and the portion of the epidermal layer contacting sensor array **108** in the region of the capacitive electrode, to be properly interpreted by the external controller. Sensor circuit **102** also includes an analog-to-digital (A/D) converter **112** processing analog voltage measurements received from sensor array **108** and generating digital representations recognized by the external controller as distance measurements of the analog measured voltages from individual capacitive electrodes within sensor array **108**. A/D converter **112** transmits these digital signals to the external controller on output bus **114**.

[0013] Sensor array **108** includes a plurality of cells **116** each containing one or more capacitive electrodes. Sensor array **108** in the exemplary embodiment contains square cells approximately 45-50 μm on a side, forming a 250 X 350 array of contiguous cells **116** within sensor array **108**. Sensor array **108** is covered by a passivation material overlying the capacitive electrodes within each cell **118**. Other active devices required to form sensor circuit **102** are formed below the capacitive electrodes.

[0014] Referring to **Figures 2A** and **2B**, diagrams of sensor arrays including resistive finger detection in accordance with a preferred embodiment of the present invention are illustrated. The cross-section depicted in **Figure 2A** is a cross-section of sensor array **108** taken at section line **A-A** depicted in **Figure 1**. Cells **116** within sensor array **108** each include at least one capacitive fingerprint sensor electrode **202**, which is employed to detect the fingerprint in accordance with the known art.

A protective layer **204**, which may be a combination of insulating and passivating layers, overlies the fingerprint sensor electrodes **202** and provides a surface on which the finger is placed.

[0015] In the present invention, sensor array **108** also includes a plurality of resistive grids **206a-206b** employed to sense the resistance of the finger when placed on the surface of the sensor array **108**. This sensed resistance is then compared to a predefined "sample" or threshold value or range. If the resistance of the finger is greater than the predefined value (or within the range), a finger is detected on the surface of sensor array **108**.

[0016] Resistive finger detection grids **206a-206b** are formed over the fingerprint sensor detection electrodes **202**, on the surface of fingerprint detection device **102** on which the finger is to be placed. Relative capacitive measurements between fingerprint sensor detection electrodes **202** will not be skewed by the presence of resistive grids **206a-206b**. Resistive sensing grids **206a-206b** are isolated from each other, but may come in contact with a finger touching the surface of fingerprint detection device **102**. When the finger is on the sensing surface of the fingerprint detection device **102**, the skin resistivity of the finger provides a resistive path from one grid **206a** to the other **206b**. Measuring the resistance between the two grids provides a means for measuring the skin resistivity of the finger. A plan view of a suitable geometry for grids **206a-206b** is illustrated in **Figure 2B**.

[0017] With reference now to **Figure 3**, a circuit diagram for a finger detection circuit employed within a fingerprint sensor in accordance with a preferred embodiment of the present invention is depicted. Within finger detection circuit **302**, resistive grids **206a-206d** are coupled to a resistance measurement and comparison unit **308**. As noted above, the resistance of a finger placed on the sensor device **102** is measured and utilized to detect a finger. This resistance will depend on the bio-characteristics of the skin on the finger, which is employed to prevent spoofing by determining whether the finger placed on the fingerprint sensor device **102** provides a resistance within a predefined range or above a predefined value.

[0018] The resistance measurement is accomplished by connecting the variable resistances representing the finger connecting resistive grids **206a-206b**, through amplifiers **304** and **306**, to a resistance measurement and comparison unit **308**, which compares the resistance between grids **206a-206b** to a reference resistance or a range of resistances. The difference in resistances is determined by the comparator portion of resistance measurement and comparison unit **308**, which generates an output signal **310** indicated whether a finger has been detected.

[0019] Depending upon the processing and memory capabilities available, the measured resistance may be compared to absolute thresholds or ranges for the entire populace, or to specific ranges for particular individuals

identified by their fingerprint, with the individual ranges of authorized individuals being dynamically updated over time to accommodate aging and seasonal variations in the relevant bio-characteristics. In addition to providing anti-spoofing protection, fingerprint acquisition by the fingerprint sensor may also be concurrently triggered by the finger detection mechanism of the present invention.

[0020] The present invention employs measurement of bio-characteristics of skin, specifically resistance of a finger placed on a sensor for fingerprint detection, to provide anti-spoofing protection and real finger detection. Other bio-characteristics of living skin tissue may also be employed in conjunction with the present invention. The resistive finger detection mechanism may be combined with the capacitive finger detection mechanism described in the related application, either utilizing separate capacitive and resistive grids or utilizing a single grid for both capacitive and resistive measurements.

[0021] While the invention has been particularly shown and described with reference to a preferred embodiment, it will be understood by those skilled in the art that various changes in form and detail may be made therein without departing from the spirit and scope of the invention.

Claims

1. A method of finger detection, comprising:

measuring a resistance between at least two isolated resistive grids on a sensing surface of a capacitive fingerprint detection device when connected by an object placed on the sensing surface of the fingerprint detection device, wherein the capacitive fingerprint detection device includes a plurality of capacitive sensor electrodes below the resistive grids for detecting fingerprint features;
comparing the measured resistance to a resistance range corresponding to living skin tissue to determine whether a finger has been placed on the surface of the fingerprint detection device.

2. The method of claim 1, further comprising:

responsive to determining that the measured resistance falls within the resistance range corresponding to living skin tissue, indicating that a finger has been placed on the surface of the fingerprint detection device.

3. The method of claim 2, wherein the step of measuring a resistance between at least two isolated resistive grids on a sensing surface of a capacitive fingerprint detection device when connected by an

object placed on the sensing surface of the fingerprint detection device further comprises:

measuring a resistance between two resistive grids connected by the object.

4. The method of claim 3, further comprising:

measuring a resistance between two resistive grids electrically connected by a finger; and responsive to determining that the measured resistance between the two resistive grids falls within the resistance range corresponding to living skin tissue, indicating that the object on the surface of the fingerprint detection device is the finger.

5. The method of claim 3, further comprising:

measuring a resistance between two resistive grids electrically connected by an object other than a finger; and responsive to determining that the measured resistance between the two resistive grids falls outside the resistance range corresponding to living skin tissue, indicating that the object on the surface of the fingerprint detection device is not a finger.

6. The method of claim 2, further comprising:

comparing the measured resistance to a threshold resistance;
responsive to determining that the measured resistance is greater than the threshold resistance, indicating that a finger has been placed on the surface of the fingerprint detection device; and
responsive to determining that the measured resistance is not greater than the threshold resistance, indicating that an object other than a finger has been placed on the surface of the fingerprint detection device.

7. Anti-spoofing protection for a fingerprint detection device, comprising:

a plurality of resistive grids overlying capacitive sensor electrodes employed within the fingerprint detection device to detect fingerprint features on a sensing surface of the fingerprint detection device;
resistance measurement means measuring a resistance between two of the resistive grids when an object on the sensing surface electrically connects the two resistive grids; and
comparator means comparing the measured resistance to resistive bio-characteristics of liv-

ing skin tissue to determine whether the object on the sensing surface of the fingerprint detection device is a finger.

8. A fingerprint detection device, comprising: 5

capacitive sensor electrodes employed to detect fingerprint features;
 a plurality of resistive grids on a sensing surface of the fingerprint detection device and 10
 overlying the capacitive sensor electrodes;
 resistance measurement means measuring a resistance between two of the resistive grids when an object on the sensing surface electrically connects the two resistive grids; and 15
 comparator means comparing the measured resistance to resistive bio-characteristics of living skin tissue to determine whether the object on the sensing surface of the fingerprint detection device is a finger. 20

9. The protection or device of claim 7 or 8, wherein the plurality of resistive grids further comprises:

the two resistive grids. 25

10. The protection or device of claim 7 or 8, wherein the plurality of resistive grids further comprises:

two resistive grids having interlocking regions 30
 adapted to be overlapped and electrically connected by an object on the sensing surface.

11. The protection or device of claim 7 or 8, wherein the comparator means further comprises: 35

means for indicating whether the object on the sensing surface of the fingerprint detection device is a finger. 40

12. The protection or device of claim 7 or 8, wherein the comparator means indicates that the object on the sensing surface of the fingerprint detection device is a finger if the measured resistance falls within a predefined range of resistances. 45

13. The protection or device of claim 7 or 8, wherein the comparator means indicates that the object on the sensing surface of the fingerprint detection device is not a finger if the measured resistance falls outside a predefined range of resistances. 50

14. The protection or device of claim 7 or 8, wherein the comparator means compares the measured resistance to a threshold resistance. 55
